empymod Documentation

Release 1.2.1

Dieter Werthmüller

Mar 11, 2017

Contents

Version: 1.2.1; Date: Mar 11, 2017

Manual for *empymod*, a one-dimensional, electromagnetic forward modeller in Python.

The **e**lectro**m**agnetic **py**thon **mod**eller *empymod* can model electric or magnetic responses due to a three-dimensional electric or magnetic source in a layered-earth model with electric vertical isotropy (ρ_h, λ), electric permittivity (ϵ_h, ϵ_v), and magnetic permeability (μ_h, μ_v), from very low frequencies ($f \to 0$ Hz) to very high frequencies ($f \to$ GHz).

Contents:

Info

The latest version of this documentation can be found at https://empymod.readthedocs.io.

Installation & requirements

The easiest way to install the latest stable version of *empymod* is via *conda*:

```
> conda install -c prisae empymod
```

or via *pip*:

```
> pip install empymod
```

Alternatively, you can download the latest version from GitHub and either add the path to *empymod* to your python-path variable, or install it in your python distribution via:

```
> python setup.py install
```

Required are python version 3.4 or higher and the modules *NumPy* and *SciPy*. If you want to run parts of the kernel in parallel, the module *numexpr* is required additionally.

If you are new to Python I recommend using a Python distribution, which will ensure that all dependencies are met, specifically properly compiled versions of *NumPy* and *SciPy*; I recommend using Anaconda (version 3.x; continuum.io/downloads). If you install Anaconda you can simply start the *Anaconda Navigator*, add the channel *prisae* and *empymod* will appear in the package list and can be installed with a click.

Usage

The main modelling routines is *bipole*, which can calculate the electromagnetic frequency- or time-domain field due to arbitrary finite electric or magnetic bipole sources, measured by arbitrary finite electric or magnetic bipole receivers.

The model is defined by horizontal resistivity and anisotropy, horizontal and vertical electric permittivities and horizontal and vertical magnetic permeabilities. By default, the electromagnetic response is normalized to to source and receiver of 1 m length, and source strength of 1 A.

A simple frequency-domain example, with most of the parameters left at the default value:

```
>>> import numpy as np
>>> from empymod import bipole
>>> # x-directed bipole source: x0, x1, y0, y1, z0, z1
>>> src = [-50, 50, 0, 0, 100, 100]
>>> # x-directed dipole source-array: x, y, z, azimuth, dip
>>> rec = [np.arange(1, 11)*500, np.zeros(10), 200, 0, 0]
>>> # layer boundaries
>>> depth = [0, 300, 1000, 1050]
>>> # layer resistivities
>>> res = [1e20, .3, 1, 50, 1]
>>> # Frequency
>>> freq = 1
>>> # Calculate electric field due to an electric source at 1 Hz.
>>> # [msrc = mrec = True (default)]
>>> EMfield = bipole(src, rec, depth, res, freq)
>>> EMfield = bipole(src, rec, depth, res, freq, verb=4)
:: empymod START  ::

Have a look at the notebooks for more extensive examples including figures.

Structure

- **model.py**: EM modelling routines.

- **utils.py**: Utilities for *model* such as checking input parameters.

- **kernel.py**: Kernel of *empymod*, calculates the wavenumber-domain electromagnetic response. Plus analytical, frequency-domain full- and half-space solutions.

- **transform.py**: Methods to carry out the required Hankel transform from wavenumber to frequency domain and Fourier transform from frequency to time domain.

- **filters.py**: Filters for the *Fast Hankel Transform* (FHT, *[Anderson_1982]*) and the *Fourier Sine and Cosine Transforms [Anderson_1975]*.

Missing features

A list of things that should or could be added and improved:

- **Kernel**

    - Include *scipy.integrate.quad* as an additional Hankel transform. There are cases when both *QWE* and *FHT* struggle, e.g. at very short offsets with very high frequencies (GPR).

    - A *cython* or *numba* (pure C?) implementation of the *kernel* and the *transform* modules. Maybe not worth it, as it may improve speed, but decrease accessibility. Both at the same time would be nice. A fast C-version for calculations (inversions), and a Python-version to tinker with for interested folks. (Probably combined with default parallelisation, removing the *numexpr* variant.)

- **More modelling routines:**

    - Convolution with a wavelet for GPR (proper version of *model.gpr*, needs another HT/FT).

    - Various source-receiver arrangements (loops etc).

    - Load and save functions to store and load model, together with all information.

- Module to create Hankel filters (nice to have addition, mainly for educational purposes).

- GUI.

- Add a benchmark suite, e.g. http://asv.readthedocs.io, in addition to the testing suite.

Testing

The modeller comes with a test suite using *pytest*. If you want to run the tests, just install *pytest* and run it within the *empymod*-top-directory.

```
> conda install pytest
> # or
> pip install pytest
> # and then
> cd to/the/empymod/folder
> ls
CHANGELOG.md   empymod   notebooks   paper        requirements.txt   tests
docs           LICENSE   NOTICE      README.rst   setup.py           THANKS.md
> # pytest will find the tests, which are located in the tests-folder.
> # simply run
> pytest
```

It should run all tests successfully. Please let me know if not!

Note that the installations via conda/pip do not have the test-suite included. To run the test-suite you must download *empymod* from GitHub.

Citation

I am in the process of publishing an article regarding *empymod*, and I will put the info here once it is reality. If you publish results for which you used *empymod*, please consider citing this article. Also consider citing *[Hunziker_et_al_2015]* and *[Key_2012]*, without which *empymod* would not exist.

Notice

This product includes software that was initially (till 01/2017) developed at *The Mexican Institute of Petroleum IMP* (*Instituto Mexicano del Petróleo*, http://www.imp.mx). The project was funded through *The Mexican National Council of Science and Technology* (*Consejo Nacional de Ciencia y Tecnología*, http://www.conacyt.mx).

This product is a derivative work of *[Hunziker_et_al_2015]* and *[Key_2012]*, and their publicly available software:

1. Hunziker, J., J. Thorbecke, and E. Slob, 2015, The electromagnetic response in a layered vertical transverse isotropic medium: A new look at an old problem: Geophysics, 80, F1-F18; DOI: 10.1190/geo2013-0411.1; Software: software.seg.org/2015/0001.

2. Key, K., 2012, Is the fast Hankel transform faster than quadrature?: Geophysics, 77, F21-F30; DOI: 10.1190/GEO2011-0237.1; Software: software.seg.org/2012/0003.

Both pieces of software are published under the *SEG disclaimer*. Parts of the modeller *emmod* from Hunziker et al, 2015, is furthermore released under the *Common Public License Version 1.0 (CPL)*. See the *NOTICE*-file in the root directory for more information and a reprint of the SEG disclaimer and the CPL.

Note on speed, memory, and accuracy

There is the usual trade-off between speed, memory, and accuracy. Very generally speaking we can say that the *FHT* is faster than *QWE*, but *QWE* is much easier on memory usage. I doubt you will ever run into memory issues with *QWE*, whereas for *FHT* you might for ten thousands of offsets or hundreds of layers. Furthermore, *QWE* allows you to control the accuracy.

There are two optimisation possibilities included via the `opt`-flag: parallelisation (`opt='parallel'`) and spline interpolation (`opt='spline'`). They are switched off by default. The optimization `opt='parallel'` only affects speed and memory usage, whereas `opt='spline'` also affects precision!

I am sure *empymod* could be made much faster with cleverer coding style or with the likes of *cython* or *numba*. Suggestions and contributions are welcomed!

Depths, Rotation, and Bipole

Depths: Calculation of many source and receiver positions is fastest if they remain at the same depth, as they can be calculated in one kernel-call. If depths do change, one has to loop over them.

Rotation: Sources and receivers aligned along the principal axes x, y, and z can be calculated in one kernel call. For arbitrary aligned di- or bipoles, 3 kernel calls are required. If source and receiver are arbitrary aligned, 3x3 hence 9 kernel calls are required.

Bipole: Bipole increase the calculation time by the amount of integration points used. For a source and a receiver bipole with each 5 integration points you need 5x5 hence 25 kernel calls. You can calculate it in 1 kernel call if you set both integration points to 1, and hence calculate the bipole as if they were dipoles at their centre.

Example: For 1 source and 10 receivers, all at the same depth, 1 kernel call is required. If all receivers are at different depths, 10 kernel calls are required. If you make source and receivers bipoles with 5 integration points, 250 kernel calls are required. If you rotate the source arbitrary horizontally, 500 kernel calls are required. If you rotate the receivers too, in the horizontal plane, 1'000 kernel calls are required. If you rotate the receivers also vertically, 1'500 kernel calls are required. If you rotate the source vertically too, 2'250 kernel calls are required. So your calculation will take 2'250 times longer! No matter how fast the kernel is, this will take a long time. Therefore carefully plan how precise you want to define your source and receiver bipoles.

Table 1.1: Example as a table for comparison: 1 source, 10 receiver (one or many frequencies).

kernel calls	source bipole			receiver bipole			
	intpts	azimuth	dip	intpts	azimuth	dip	diff. z
1	1	0/90	0/90	1	0/90	0/90	1
10	1	0/90	0/90	1	0/90	0/90	10
250	5	0/90	0/90	5	0/90	0/90	10
500	5	arb.	0/90	5	0/90	0/90	10
1000	5	arb.	0/90	5	arb.	0/90	10
1500	5	arb.	0/90	5	arb.	arb.	10
2250	5	arb.	arb.	5	arb.	arb.	10

Parallelisation

If `opt = 'parallel'`, a good dozen of the most time-consuming statements are calculated by using the *numexpr* package (https://github.com/pydata/numexpr/wiki/Numexpr-Users-Guide). These statements are all in the *kernel*-functions *greenfct*, *reflections*, and *fields*, and all involve Γ in one way or another, often calculating square roots or exponentials. As Γ has dimensions (#frequencies, #offsets, #layers, #lambdas), it can become fairly big.

The module *numexpr* uses by default all available cores up to a maximum of 8. You can change this behaviour to a lower or a higher value with the following command (in the example it is changed to 4):

```
>>> import numexpr
>>> numexpr.set_num_threads(4)
```

This parallelisation will make *empymod* faster if you calculate a lot of offsets/frequencies at once, but slower for few offsets/frequencies. Best practice is to check first which one is faster. (You can use the included *jupyter notebook-*benchmark.)

Spline interpolation

If `opt = 'spline'`, the so-called *lagged convolution* or *splined* variant of the *FHT* (depending on `htarg`) or the *splined* version of the *QWE* are applied. The spline option should be used with caution, as it is an interpolation and therefore less precise than the non-spline version. However, it significantly speeds up *QWE*, and massively speeds up *FHT*. (The *numexpr*-version of the spline option is slower than the pure spline one, and therefore it is only possible to have either `'parallel'` or `'spline'` on.)

Setting `opt = 'spline'` is generally faster. Good speed-up is achieved for *QWE* by setting `maxint` as low as possible. Also, the higher `nquad` is, the higher the speed-up will be. The variable `pts_per_dec` has also some influence. For *FHT*, big improvements are achieved for long FHT-filters and for many offsets/frequencies (thousands). Additionally, spline minimizes memory requirements a lot. Speed-up is greater if all source-receiver angles are identical.

FHT: Default for `pts_per_dec = None`, which is the original *lagged convolution*, where the spacing is defined by the filter-base, the transform is carried out first followed by spline-interpolation. You can set this parameter to an integer, which defines the number of points to evaluate per decade. In this case the spline-interpolation is carried out first, followed by the transformation. The original *lagged convolution* is generally the fastest for a very good precision. However, by setting `pts_per_dec` appropriately one can achieve higher precision, normally at the cost of speed.

> **Warning:** Keep in mind that it uses interpolation, and is therefore not as accurate as the non-spline version. Use with caution and always compare with the non-spline version if you can apply the spline-version to your problem at hand!

Be aware that the *QWE*- and the *FHT*-Versions for the frequency-to-time transformation *always* use the splined version and *always* loop over offsets.

Looping

By default, you can calculate many offsets and many frequencies all in one go, vectorized (for the *FHT*), which is the default. The `loop` parameter gives you the possibility to force looping over frequencies or offsets. This parameter can have severe effects on both runtime and memory usage. Play around with this factor to find the fastest version for your problem at hand. It ALWAYS loops over frequencies if `ht = 'QWE'` or if `opt = 'spline'`. All vectorized is very fast if there are few offsets or few frequencies. If there are many offsets and many frequencies, looping over the smaller of the two will be faster. Choosing the right looping together with `opt = 'parallel'` can have a huge influence.

Vertical components

It is advised to use `xdirect = True` (the default) if source and receiver are in the same layer to calculate

- the vertical electric field due to a vertical electric source,
- configurations that involve vertical magnetic components (source or receiver),
- all configurations when source and receiver depth are exactly the same.

The Hankel transforms methods are having sometimes difficulties transforming these functions.

FFTLog

FFTLog is the logarithmic analogue to the Fast Fourier Transform FFT originally proposed by *[Talman_1978]*. The code used by *empymod* was published in Appendix B of *[Hamilton_2000]* and is publicly available at casa.colorado.edu/~ajsh/FFTLog. From the *FFTLog*-website:

FFTLog is a set of fortran subroutines that compute the fast Fourier or Hankel (= Fourier-Bessel) transform of a periodic sequence of logarithmically spaced points.

FFTlog can be used for the Hankel as well as for the Fourier Transform, but currently *empymod* uses it only for the Fourier transform. It uses a simplified version of the python implementation of FFTLog, *pyfftlog* (github.com/prisae/pyfftlog).

References

Code

`model` – **Model EM-responses**

EM-modelling routines. The implemented routines might not be the fastest solution to your specific problem. Use these routines as template to create your own, problem-specific modelling routine!

Principal routines:

- *bipole*
- *dipole*

The main routine is *bipole*, which can model bipole source(s) and bipole receiver(s) of arbitrary direction, for electric or magnetic sources and receivers, both in frequency and in time. A subset of *bipole* is *dipole*, which models infinitesimal small dipoles along the principal axes x, y, and z.

These principal routines make use of the following two core routines:

- *fem*: **Calculate wavenumber-domain electromagnetic field and carry out** the Hankel transform to the frequency domain.
- *tem*: Carry out the Fourier transform to time domain after *fem*.

Two further routines are shortcuts for frequency- and time-domain dipoles, respectively, and mainly in for legacy reasons:

- *frequency*: Shortcut of *dipole* for frequency-domain calculation.
- *time*: Shortcut of *dipole* for time-domain calculation.

Two more routines are more kind of examples and cannot be regarded stable; they can serve as template to create your own routines:

- *gpr*: Calculate the Ground-Penetrating Radar (GPR) response.
- *wavenumber*: Calculate the electromagnetic wavenumber-domain solution.

`empymod.model.`**`bipole`**(*src*, *rec*, *depth*, *res*, *freqtime*, *signal=None*, *aniso=None*, *epermH=None*, *epermV=None*, *mpermH=None*, *mpermV=None*, *msrc=False*, *srcpts=1*, *mrec=False*, *recpts=1*, *strength=0*, *xdirect=True*, *ht='fht'*, *htarg=None*, *ft='sin'*, *ftarg=None*, *opt=None*, *loop=None*, *verb=2*)

Return the electromagnetic field due to an electromagnetic source.

Calculate the electromagnetic frequency- or time-domain field due to arbitrary finite electric or magnetic bipole sources, measured by arbitrary finite electric or magnetic bipole receivers. By default, the electromagnetic response is normalized to to source and receiver of 1 m length, and source strength of 1 A.

>
>> Anisotropies lambda = sqrt(rho_v/rho_h) (-); #aniso = #res. Defaults to ones.
>
> **epermH, epermV** : array_like, optional

Relative horizontal/vertical electric permittivities epsilon_h/epsilon_v (-); #epermH = #epermV = #res. Default is ones.

mpermH, mpermV : array_like, optional

Relative horizontal/vertical magnetic permeabilities mu_h/mu_v (-); #mpermH = #mpermV = #res. Default is ones.

msrc, mrec : boolean, optional

If True, source/receiver (msrc/mrec) is magnetic, else electric. Default is False.

srcpts, recpts : int, optional

Number of integration points for bipole source/receiver, default is 1:

- srcpts/recpts < 3 : bipole, but calculated as dipole at centre

- srcpts/recpts >= 3 : bipole

strength : float, optional

Source strength (A):

- If 0, output is normalized to source and receiver of 1 m length, and source strength of 1 A.

- If != 0, output is returned for given source and receiver length, and source strength.

Default is 0.

xdirect : bool, optional

If True and source and receiver are in the same layer, the direct field is calculated analytically in the frequency domain, if False it is calculated in the wavenumber domain. Defaults to True.

ht : {'fht', 'qwe'}, optional

Flag to choose either the *Fast Hankel Transform* (FHT) or the *Quadrature-With-Extrapolation* (QWE) for the Hankel transform. Defaults to 'fht'.

htarg : str or filter from empymod.filters or array_like, optional

Depends on the value for *ht*:

- If *ht* = 'fht': array containing: [filter, pts_per_dec]:

  – **filter: string of filter name in *empymod.filters* or** the filter method itself. (default: *empymod.filters.key_201_2009()*)

  – **pts_per_dec: points per decade (only relevant if spline=True)**

    If none, standard lagged convolution is used. (default: None)

- If *ht* = 'qwe': array containing: [rtol, atol, nquad, maxint, pts_per_dec]:

  – rtol: relative tolerance (default: 1e-12)

  – atol: absolute tolerance (default: 1e-30)

  – nquad: order of Gaussian quadrature (default: 51)

  – maxint: maximum number of partial integral intervals (default: 40)

  – pts_per_dec: points per decade (only relevant if opt='spline') (default: 80)

  All are optional, you only have to maintain the order. To only change *nquad* to 11 and use the defaults otherwise, you can provide htarg=['', '', 11].

ft : {'sin', 'cos', 'qwe', 'fftlog'}, optional

> Only used if *signal* != None. Flag to choose either the Sine- or Cosine-Filter, the Quadrature-With-Extrapolation (QWE), or FFTLog for the Fourier transform. Defaults to 'sin'.

ftarg : str or filter from empymod.filters or array_like, optional

> **Only used if *signal* !=None. Depends on the value for *ft*:**
>
> - If *ft* = 'sin' or 'cos': array containing: [filter, pts_per_dec]:
>
>   - **filter: string of filter name in *empymod.filters* or** the filter method itself. (Default: *empymod.filters.key_201_CosSin_2012()*)
>
>   - **pts_per_dec: points per decade. If none, standard lagged** convolution is used. (Default: None)
>
> - If *ft* = 'qwe': array containing: [rtol, atol, nquad, maxint, pts_per_dec]:
>
>   - rtol: relative tolerance (default: 1e-8)
>
>   - atol: absolute tolerance (default: 1e-20)
>
>   - nquad: order of Gaussian quadrature (default: 21)
>
>   - maxint: maximum number of partial integral intervals (default: 200)
>
>   - pts_per_dec: points per decade (only relevant if spline=True) (default: 20)
>
> All are optional, you only have to maintain the order. To only change *nquad* to 11 and use the defaults otherwise, you can provide ftarg=['', '', 11].
>
> - If *ft* = 'fftlog': array containing: [pts_per_dec, add_dec, q]:
>
>   - pts_per_dec: sampels per decade (default: 10)
>
>   - add_dec: additional decades [left, right] (default: [-2, 1])
>
>   - q: exponent of power law bias (default: 0); -1 <= q <= 1
>
> All are optional, you only have to maintain the order. To only change *add_dec* to [-1, 1] and use the defaults otherwise, you can provide ftarg=['', [-1, 1]].

opt : {None, 'parallel', 'spline'}, optional

> **Optimization flag. Defaults to None:**
>
> - None: Normal case, no parallelization nor interpolation is used.
>
> - If 'parallel', the package *numexpr* is used to evaluate the most expensive statements. Always check if it actually improves performance for a specific problem. It can speed up the calculation for big arrays, but will most likely be slower for small arrays. It will use all available cores for these specific statements, which all contain *Gamma* in one way or another, which has dimensions (#frequencies, #offsets, #layers, #lambdas), therefore can grow pretty big. The module *numexpr* uses by default all available cores up to a maximum of 8. You can change this behaviour to your desired number of threads *nthreads* with *numexpr.set_num_threads(nthreads)*.

- If 'spline', the *lagged convolution* or *splined* variant of the FHT or the *splined* version of the QWE are used. Use with caution and check with the non-spline version for a specific problem. (Can be faster, slower, or plainly wrong, as it uses interpolation.) If spline is set it will make use of the parameter pts_per_dec that can be defined in htarg. If pts_per_dec is not set for FHT, then the *lagged* version is used, else the *splined*.

  The option 'parallel' only affects speed and memory usage, whereas 'spline' also affects precision! Please read the note in the *README* documentation for more information.

loop : {None, 'freq', 'off'}, optional

  Define if to calculate everything vectorized or if to loop over frequencies ('freq') or over offsets ('off'), default is None. It always loops over frequencies if `ht = 'qwe'` or if `opt = 'spline'`. Calculating everything vectorized is fast for few offsets OR for few frequencies. However, if you calculate many frequencies for many offsets, it might be faster to loop over frequencies. Only comparing the different versions will yield the answer for your specific problem at hand!

verb : {0, 1, 2, 3, 4}, optional

  Level of verbosity, default is 2:

  - 0: Print nothing.
  - 1: Print warnings.
  - 2: Print additional runtime and kernel calls
  - 3: Print additional start/stop, condensed parameter information.
  - 4: Print additional full parameter information

Returns **EM** : ndarray, (nfreq, nrec, nsrc)

  Frequency- or time-domain EM field (depending on *signal*):

  - If rec is electric, returns E [V/m].
  - If rec is magnetic, returns B [T] (not H [A/m]!).

  In the case of the impulse time-domain response, the unit is further divided by seconds [1/s].

  However, source and receiver are normalised (unless strength != 0). So for instance in the electric case the source strength is 1 A and its length is 1 m. So the electric field could also be written as [V/(A.m2)].

  The shape of EM is (nfreq, nrec, nsrc). However, single dimensions are removed.

empymod.model.**dipole**(*src*, *rec*, *depth*, *res*, *freqtime*, *signal=None*, *ab=11*, *aniso=None*, *epermH=None*, *epermV=None*, *mpermH=None*, *mpermV=None*, *xdirect=True*, *ht='fht'*, *htarg=None*, *ft='sin'*, *ftarg=None*, *opt=None*, *loop=None*, *verb=2*)

Return the electromagnetic field due to a dipole source.

Calculate the electromagnetic frequency- or time-domain field due to infinitesimal small electric or magnetic dipole source(s), measured by infinitesimal small electric or magnetic dipole receiver(s); sources and receivers are directed along the principal directions x, y, or z, and all sources are at the same depth, as well as all receivers are at the same depth.

Use the functions *bipole* to calculate dipoles with arbitrary angles or bipoles of finite length and arbitrary angle.

The function *dipole* could be replaced by *bipole* (all there is to do is translate *ab* into *msrc*, *mrec*, *azimuth*'s and *dip*'s). However, *dipole* is kept separately to serve as an example of a simple modelling routine that can serve as a template.

Parameters **src, rec** : list of floats or arrays

> Source and receiver coordinates (m): [x, y, z]. The x- and y-coordinates can be arrays, z is a single value. The x- and y-coordinates must have the same dimension.

depth : list

> Absolute layer interfaces z (m); #depth = #res - 1 (excluding +/- infinity).

res : array_like

> Horizontal resistivities rho_h (Ohm.m); #res = #depth + 1.

freqtime : array_like

> Frequencies f (Hz) if *signal* == None, else times t (s).

signal : {None, 0, 1, -1}, optional

> **Source signal, default is None:**
>
> > - None: Frequency-domain response
> >
> > - -1 : Switch-off time-domain response
> >
> > - 0 : Impulse time-domain response
> >
> > - +1 : Switch-on time-domain response

ab : int, optional

> Source-receiver configuration, defaults to 11.

		electric source			magnetic source		
		x	**y**	**z**	**x**	**y**	**z**
electric	**x**	11	12	13	14	15	16
	y	21	22	23	24	25	26
receiver	**z**	31	32	33	34	35	36
magnetic	**x**	41	42	43	44	45	46
	y	51	52	53	54	55	56
receiver	**z**	61	62	63	64	65	66

aniso : array_like, optional

> Anisotropies lambda = sqrt(rho_v/rho_h) (-); #aniso = #res. Defaults to ones.

epermH, epermV : array_like, optional

> Relative horizontal/vertical electric permittivities epsilon_h/epsilon_v (-); #epermH = #epermV = #res. Default is ones.

mpermH, mpermV : array_like, optional

> Relative horizontal/vertical magnetic permeabilities mu_h/mu_v (-); #mpermH = #mpermV = #res. Default is ones.

xdirect : bool, optional

> If True and source and receiver are in the same layer, the direct field is calculated analytically in the frequency domain, if False it is calculated in the wavenumber domain. Defaults to True.

ht : {'fht', 'qwe'}, optional

> Flag to choose either the *Fast Hankel Transform* (FHT) or the *Quadrature-With-Extrapolation* (QWE) for the Hankel transform. Defaults to 'fht'.

htarg : str or filter from empymod.filters or array_like, optional

> **Depends on the value for *ht*:**
>
> - If *ht* = 'fht': array containing: [filter, pts_per_dec]:
>
>   - **filter: string of filter name in *empymod.filters* or** the filter method itself. (default: *empymod.filters.key_201_2009()*)
>
>   - **pts_per_dec: points per decade (only relevant if spline=True)**
>
>   **If none, standard lagged convolution is used.** (default: None)
>
> - If *ht* = 'qwe': array containing: [rtol, atol, nquad, maxint, pts_per_dec]:
>
>   - rtol: relative tolerance (default: 1e-12)
>
>   - atol: absolute tolerance (default: 1e-30)
>
>   - nquad: order of Gaussian quadrature (default: 51)
>
>   - maxint: maximum number of partial integral intervals (default: 40)
>
>   - pts_per_dec: points per decade (only relevant if opt='spline') (default: 80)
>
> All are optional, you only have to maintain the order. To only change *nquad* to 11 and use the defaults otherwise, you can provide htarg=['', '', 11].

ft : {'sin', 'cos', 'qwe', 'fftlog'}, optional

> Only used if *signal* != None. Flag to choose either the Sine- or Cosine-Filter, the Quadrature-With-Extrapolation (QWE), or FFTLog for the Fourier transform. Defaults to 'sin'.

ftarg : str or filter from empymod.filters or array_like, optional

> **Only used if *signal* !=None. Depends on the value for *ft*:**
>
> - If *ft* = 'sin' or 'cos': array containing: [filter, pts_per_dec]:
>
>   - **filter: string of filter name in *empymod.filters* or** the filter method itself. (Default: *empymod.filters.key_201_CosSin_2012()*)
>
>   - **pts_per_dec: points per decade. If none, standard lagged** convolution is used. (Default: None)
>
> - If *ft* = 'qwe': array containing: [rtol, atol, nquad, maxint, pts_per_dec]:

  - rtol: relative tolerance (default: 1e-8)

  - atol: absolute tolerance (default: 1e-20)

  - nquad: order of Gaussian quadrature (default: 21)

  - maxint: maximum number of partial integral intervals (default: 200)

  - pts_per_dec: points per decade (only relevant if spline=True) (default: 20)

  All are optional, you only have to maintain the order. To only change *nquad* to 11 and use the defaults otherwise, you can provide ftarg=['', '', 11].

- If *ft* = 'fftlog': array containing: [pts_per_dec, add_dec, q]:

  - pts_per_dec: sampels per decade (default: 10)

  - add_dec: additional decades [left, right] (default: [-2, 1])

  - q: exponent of power law bias (default: 0); -1 <= q <= 1

  All are optional, you only have to maintain the order. To only change *add_dec* to [-1, 1] and use the defaults otherwise, you can provide ftarg=['', [-1, 1]].

opt : {None, 'parallel', 'spline'}, optional

  Optimization flag. Defaults to None:

  - None: Normal case, no parallelization nor interpolation is used.

  - If 'parallel', the package *numexpr* is used to evaluate the most expensive statements. Always check if it actually improves performance for a specific problem. It can speed up the calculation for big arrays, but will most likely be slower for small arrays. It will use all available cores for these specific statements, which all contain *Gamma* in one way or another, which has dimensions (#frequencies, #offsets, #layers, #lambdas), therefore can grow pretty big. The module *numexpr* uses by default all available cores up to a maximum of 8. You can change this behaviour to your desired number of threads *nthreads* with *numexpr.set_num_threads(nthreads)*.

  - If 'spline', the *lagged convolution* or *splined* variant of the FHT or the *splined* version of the QWE are used. Use with caution and check with the non-spline version for a specific problem. (Can be faster, slower, or plainly wrong, as it uses interpolation.) If spline is set it will make use of the parameter pts_per_dec that can be defined in htarg. If pts_per_dec is not set for FHT, then the *lagged* version is used, else the *splined*.

  The option 'parallel' only affects speed and memory usage, whereas 'spline' also affects precision! Please read the note in the *README* documentation for more information.

loop : {None, 'freq', 'off'}, optional

  Define if to calculate everything vectorized or if to loop over frequencies ('freq') or over offsets ('off'), default is None. It always loops over frequencies if ht = 'qwe' or if opt = 'spline'. Calculating everything vectorized is fast for few offsets OR for few frequencies. However, if you calculate many frequencies

for many offsets, it might be faster to loop over frequencies. Only comparing the different versions will yield the answer for your specific problem at hand!

verb : {0, 1, 2, 3, 4}, optional

Level of verbosity, default is 2:

- 0: Print nothing.

- 1: Print warnings.

- 2: Print additional runtime and kernel calls

- 3: Print additional start/stop, condensed parameter information.

- 4: Print additional full parameter information

Returns **EM** : ndarray, (nfreq, nrec, nsrc)

Frequency- or time-domain EM field (depending on *signal*):

- If rec is electric, returns E [V/m].

- If rec is magnetic, returns B [T] (not H [A/m]!).

In the case of the impulse time-domain response, the unit is further divided by seconds [1/s].

However, source and receiver are normalised. So for instance in the electric case the source strength is 1 A and its length is 1 m. So the electric field could also be written as [V/(A.m2)].

The shape of EM is (nfreq, nrec, nsrc). However, single dimensions are removed.

```

empymod.model.**gpr**(*src*, *rec*, *depth*, *res*, *fc=250*, *ab=11*, *gain=None*, *aniso=None*, *epermH=None*, *epermV=None*, *mpermH=None*, *mpermV=None*, *xdirect=True*, *ht='fht'*, *htarg=None*, *opt=None*, *loop='off'*, *verb=2*)

Return the Ground-Penetrating Radar signal.

THIS FUNCTION IS IN DEVELOPMENT, USE WITH CAUTION.

Or in other words it is merely an example how one could calculate the GPR-response. However, the currently included *FHT* and *QWE* struggle for these high frequencies, and another Hankel transform has to be included to make GPR work properly (e.g. *scipy.integrate.quad*).

- *QWE* is slow, but does a pretty good job except for very short offsets: only direct wave for offset < 0.1 m, triangle-like noise at later times.
- *FHT* is fast. Airwave, direct wave and first reflection are well visible, but afterwards it is very noisy.

A lot is still hard-coded in this routine, for instance the frequency-range used to calculate the response.

For input parameters see *frequency*, except for:

> **Parameters fc** : float
>
>> Centre frequency of GPR-signal (MHz). Sensible values are between 10 MHz and 3000 MHz.
>
> **gain** : float
>
>> Power of gain function. If None, no gain is applied.
>
> **Returns t** : array
>
>> Times (s)
>
> **gprEM** : ndarray
>

empymod.model.**wavenumber**(*src*, *rec*, *depth*, *res*, *freq*, *wavenumber*, *ab=11*, *aniso=None*, *epermH=None*, *epermV=None*, *mpermH=None*, *mpermV=None*, *xdirect=True*, *verb=2*)

Return the electromagnetic wavenumber-domain field.

Calculate the electromagnetic wavenumber-domain field due to infinitesimal small electric or magnetic dipole source(s), measured by infinitesimal small electric or magnetic dipole receiver(s); sources and receivers are directed along the principal directions x, y, or z, and all sources are at the same depth, as well as all receivers are at the same depth.

> **Parameters src, rec** : list of floats or arrays
>
>> Source and receiver coordinates (m): [x, y, z]. The x- and y-coordinates can be arrays, z is a single value. The x- and y-coordinates must have the same dimension. The x- and y-coordinates only matter for the angle-dependent factor.
>
> **depth** : list
>
>> Absolute layer interfaces z (m); #depth = #res - 1 (excluding +/- infinity).
>
> **res** : array_like
>
>> Horizontal resistivities rho_h (Ohm.m); #res = #depth + 1.
>
> **freq** : array_like
>
>> Frequencies f (Hz), used to calculate etaH/V and zetaH/V.
>
> **wavenumber** : array
>
>> Wavenumbers lambda (1/m)
>
> **ab** : int, optional
>
>> Source-receiver configuration, defaults to 11.

		electric source			magnetic source		
		x	**y**	**z**	**x**	**y**	**z**
electric	**x**	11	12	13	14	15	16
	y	21	22	23	24	25	26
receiver	**z**	31	32	33	34	35	36
magnetic	**x**	41	42	43	44	45	46
	y	51	52	53	54	55	56
receiver	**z**	61	62	63	64	65	66

aniso : array_like, optional

Anisotropies lambda = sqrt(rho_v/rho_h) (-); #aniso = #res. Defaults to ones.

epermH, epermV : array_like, optional

Relative horizontal/vertical electric permittivities epsilon_h/epsilon_v (-); #epermH = #epermV = #res. Default is ones.

mpermH, mpermV : array_like, optional

Relative horizontal/vertical magnetic permeabilities mu_h/mu_v (-); #mpermH = #mpermV = #res. Default is ones.

xdirect : bool, optional

If True and source and receiver are in the same layer, the direct field is calculated analytically in the frequency domain, if False it is calculated in the wavenumber domain. Defaults to True.

verb : {0, 1, 2, 3, 4}, optional

Level of verbosity, default is 2:

- 0: Print nothing.

- 1: Print warnings.

- 2: Print additional runtime and kernel calls

- 3: Print additional start/stop, condensed parameter information.

- 4: Print additional full parameter information

Returns **PJ0, PJ1** : array

Wavenumber-domain EM responses:

- PJ0: Wavenumber-domain solution for the kernel with a Bessel function of the first kind of order zero.

- PJ1: Wavenumber-domain solution for the kernel with a Bessel function of the first kind of order one.

> Return the electromagnetic frequency-domain response.

> This function is called from one of the above modelling routines. No input-check is carried out here. See the main description of `model` for information regarding input and output parameters.

> This function can be directly used if you are sure the provided input is in the correct format. This is useful for inversion routines and similar, as it can speed-up the calculation by omitting input-checks.

empymod.model.**tem**(*fEM*, *off*, *freq*, *time*, *signal*, *ft*, *ftarg*, *conv=True*)

> Return the time-domain response of the frequency-domain response fEM.

> This function is called from one of the above modelling routines. No input-check is carried out here. See the main description of `model` for information regarding input and output parameters.

> This function can be directly used if you are sure the provided input is in the correct format. This is useful for inversion routines and similar, as it can speed-up the calculation by omitting input-checks.

kernel – Kernel calculation

Kernel of *empymod*, calculates the wavenumber-domain electromagnetic response. Plus analytical, frequency-domain full- and half-space solutions.

The functions 'wavenumber', 'angle_factor', 'fullspace', 'greenfct', 'reflections', and 'fields' are based on source files (specified in each function) from the source code distributed with *[Hunziker_et_al_2015]*, which can be found at soft-ware.seg.org/2015/0001. These functions are (c) 2015 by Hunziker et al. and the Society of Exploration Geophysicists, http://software.seg.org/disclaimer.txt. Please read the NOTICE-file in the root directory for more information regarding the involved licenses.

empymod.kernel.**wavenumber**(*zsrc*, *zrec*, *lsrc*, *lrec*, *depth*, *etaH*, *etaV*, *zetaH*, *zetaV*, *lambd*, *ab*, *xdirect*, *msrc*, *mrec*, *use_ne_eval*)

> Calculate wavenumber domain solution.

Return the wavenumber domain solutions *PJ0*, *PJ1*, and *PJ0b*, which have to be transformed with a Hankel transform to the frequency domain. *PJ0/PJ0b* and *PJ1* have to be transformed with Bessel functions of order 0 (J_0) and 1 (J_1), respectively.

This function corresponds loosely to equations 105–107, 111–116, 119–121, and 123–128 in *[Hunziker_et_al_2015]*, and equally loosely to the file *kxwmod.c*.

[Hunziker_et_al_2015] uses Bessel functions of orders 0, 1, and 2 (J_0, J_1, J_2). The implementations of the *Fast Hankel Transform* and the *Quadrature-with-Extrapolation* in *transform* are set-up with Bessel functions of order 0 and 1 only. This is achieved by applying the recurrence formula

$$J_2(kr) = \frac{2}{kr} J_1(kr) - J_0(kr) \ .$$

Note: *PJ0* and *PJ0b* could theoretically be added here into one, and then be transformed in one go. However, *PJ0b* has to be multiplied by *factAng* later. This has to be done after the Hankel transform for methods which make use of spline interpolation, in order to work for offsets that are not in line with each other.

This function is called from one of the Hankel functions in `transform`. Consult the modelling routines in `model` for a description of the input and output parameters.

If you are solely interested in the wavenumber-domain solution you can call this function directly. However, you have to make sure all input arguments are correct, as no checks are carried out here.

empymod.kernel.**angle_factor**(*angle*, *ab*, *msrc*, *mrec*)
Return the angle-dependent factor.

The whole calculation in the wavenumber domain is only a function of the distance between the source and the receiver, it is independent of the angel. The angle-dependency is this factor, which can be applied to the corresponding parts in the wavenumber or in the frequency domain.

The *angle_factor* corresponds to the sine and cosine-functions in Eqs 105-107, 111-116, 119-121, 123-128.

This function is called from one of the Hankel functions in `transform`. Consult the modelling routines in `model` for a description of the input and output parameters.

empymod.kernel.**fullspace**(*off*, *angle*, *zsrc*, *zrec*, *etaH*, *etaV*, *zetaH*, *zetaV*, *ab*, *msrc*, *mrec*)
Analytical full-space solutions in the frequency domain.

$$\hat{G}^{ee}_{\alpha\beta}, \hat{G}^{ee}_{3\alpha}, \hat{G}^{ee}_{33}, \hat{G}^{em}_{\alpha\beta}, \hat{G}^{em}_{\alpha 3}$$

This function corresponds to equations 45–50 in *[Hunziker_et_al_2015]*, and loosely to the corresponding files *Gin11.F90*, *Gin12.F90*, *Gin13.F90*, *Gin22.F90*, *Gin23.F90*, *Gin31.F90*, *Gin32.F90*, *Gin33.F90*, *Gin41.F90*, *Gin42.F90*, *Gin43.F90*, *Gin51.F90*, *Gin52.F90*, *Gin53.F90*, *Gin61.F90*, and *Gin62.F90*.

This function is called from one of the modelling routines in `model`. Consult these modelling routines for a description of the input and output parameters.

empymod.kernel.**greenfct**(*zsrc*, *zrec*, *lsrc*, *lrec*, *depth*, *etaH*, *etaV*, *zetaH*, *zetaV*, *lambd*, *ab*, *xdirect*, *msrc*, *mrec*, *use_ne_eval*)
Calculate Green's function for TM and TE.

$$\tilde{g}^{tm}_{hh}, \tilde{g}^{tm}_{hz}, \tilde{g}^{tm}_{zh}, \tilde{g}^{tm}_{zz}, \tilde{g}^{te}_{hh}, \tilde{g}^{te}_{zz}$$

This function corresponds to equations 108–110, 117/118, 122; 89–94, A18–A23, B13–B15; 97–102 A26–A31, and B16–B18 in *[Hunziker_et_al_2015]*, and loosely to the corresponding files *Gamma.F90*, *Wprop.F90*, *Ptotalx.F90*, *Ptotalxm.F90*, *Ptotaly.F90*, *Ptotalym.F90*, *Ptotalz.F90*, and *Ptotalzm.F90*.

The Green's functions are multiplied according to Eqs 105-107, 111-116, 119-121, 123-128; with the factors inside the integrals.

This function is called from the function `kernel.wavenumber`.

empymod.kernel.**reflections**(*depth, e_zH, Gam, lrec, lsrc, use_ne_eval*)

Calculate Rp, Rm.

$$R_n^\pm, \bar{R}_n^\pm$$

This function corresponds to equations 64/65 and A-11/A-12 in *[Hunziker_et_al_2015]*, and loosely to the corresponding files *Rmin.F90* and *Rplus.F90*.

This function is called from the function `kernel.greenfct`.

empymod.kernel.**fields**(*depth, Rp, Rm, Gam, lrec, lsrc, zsrc, ab, TM, use_ne_eval*)

Calculate Pu+, Pu-, Pd+, Pd-.

$$P_s^{u\pm}, P_s^{d\pm}, \bar{P}_s^{u\pm}, \bar{P}_s^{d\pm}; P_{s-1}^{u\pm}, P_n^{u\pm}, \bar{P}_{s-1}^{u\pm}, \bar{P}_n^{u\pm}; P_{s+1}^{d\pm}, P_n^{d\pm}, \bar{P}_{s+1}^{d\pm}, \bar{P}_n^{d\pm}$$

This function corresponds to equations 81/82, 95/96, 103/104, A-8/A-9, A-24/A-25, and A-32/A-33 in *[Hunziker_et_al_2015]*, and loosely to the corresponding files *Pdownmin.F90*, *Pdownplus.F90*, *Pupmin.F90*, and *Pdownmin.F90*.

This function is called from the function `kernel.greenfct`.

empymod.kernel.**halfspace**(*xco, yco, zsrc, zrec, res, freq, aniso=1, ab=11*)

Return frequency-space domain VTI half-space solution.

Calculates the frequency-space domain electromagnetic response for a half-space below air using the diffusive approximation, as given in *[Slob_et_al_2010]*.

This routine is not strictly part of *empymod* and not used by it. However, it can be useful to compare the code to the analytical solution.

There are a few known typos in the equations of *[Slob_et_al_2010]*. Write the authors to receive an updated version!

This could be integrated into *empymod* by checking if the top-layer is a very resistive layer, hence air, and the rest is a half-space, and then calling this function instead of *wavenumber*. (Similar to the way *fullspace* is incorporated if all layer parameters are identical.) The time-space domain solution could be implemented as well.

> **Parameters** **xco, yco** : array
>
> > Inline and crossline coordinates (m)
>
> **zsrc, zrec** : float
>
> > Source and receiver depth (m)
>
> **res** : float or array
>
> > Half-space resistivity (Ohm.m)
>
> **freq** : float
>
> > Frequency (Hz)
>
> **aniso** : float, optional
>
> > Anisotropy (-), default = 1
>
> **ab** : int, optional
>
> > Src-Rec config, default = 11; {11, 12, 13, 21, 22, 23, 31, 32, 33}
>
> **Returns** EM half-space solution

Examples

```
>>> from empymod.kernel import halfspace
>>> EM = halfspace(1000, 0, 10, 1, 10, 1)
>>> print('HS response : ', EM)
HS response :  (3.02186073352e-09-3.87322421836e-10j)
```

`transform` – Hankel and Fourier Transforms

Methods to carry out the required Hankel transform from wavenumber to frequency domain and Fourier transform from frequency to time domain.

The functions for the QWE and FHT Hankel and Fourier transforms are based on source files (specified in each function) from the source code distributed with *[Key_2012]*, which can be found at software.seg.org/2012/0003. These functions are (c) 2012 by Kerry Key and the Society of Exploration Geophysicists, http://software.seg.org/disclaimer. txt. Please read the NOTICE-file in the root directory for more information regarding the involved licenses.

empymod.transform.**fht** (*zsrc*, *zrec*, *lsrc*, *lrec*, *off*, *angle*, *depth*, *ab*, *etaH*, *etaV*, *zetaH*, *zetaV*, *xdirect*, *fhtarg*, *use_spline*, *use_ne_eval*, *msrc*, *mrec*)
Hankel Transform using the Fast Hankel Transform.

The *Fast Hankel Transform* is a *Digital Filter Method*, introduced to geophysics by *[Gosh_1971]*, and made popular and wide-spread by *[Anderson_1975]*, *[Anderson_1979]*, *[Anderson_1982]*.

This implementation of the FHT follows *[Key_2012]*, equation 6. Without going into the mathematical details (which can be found in any of the above papers) and following *[Key_2012]*, the FHT method rewrites the Hankel transform of the form

$$F(r) = \int_0^\infty f(\lambda) J_v(\lambda r) \mathrm{d}\lambda$$

as

$$F(r) = \sum_{i=1}^n f(b_i/r) h_i/r \ ,$$

where h is the digital filter. The Filter abscissae b is given by

$$b_i = \lambda_i r = e^{ai}, \qquad i = -l, -l+1, \cdots, l \ ,$$

with $l = (n-1)/2$, and a is the spacing coefficient.

This function is loosely based on *get_CSEM1D_FD_FHT.m* from the source code distributed with *[Key_2012]*.

The function is called from one of the modelling routines in `model`. Consult these modelling routines for a description of the input and output parameters.

> **Returns** **fEM** : array
>
>> Returns frequency-domain EM response.
>
> **kcount** : int
>
>> Kernel count. For FHT, this is 1.
>
> **conv** : bool
>
>> Only relevant for QWE, not for FHT.

empymod.transform.**hqwe**(*zsrc*, *zrec*, *lsrc*, *lrec*, *off*, *angle*, *depth*, *ab*, *etaH*, *etaV*, *zetaH*, *zetaV*, *xdirect*, *qweargs*, *use_spline*, *use_ne_eval*, *msrc*, *mrec*)

Hankel Transform using Quadrature-With-Extrapolation.

Quadrature-With-Extrapolation was introduced to geophysics by *[Key_2012]*. It is one of many so-called *ISE* methods to solve Hankel Transforms, where *ISE* stands for Integration, Summation, and Extrapolation.

Following *[Key_2012]*, but without going into the mathematical details here, the QWE method rewrites the Hankel transform of the form

$$F(r) = \int_0^\infty f(\lambda) J_v(\lambda r) \mathrm{d}\lambda$$

as a quadrature sum which form is similar to the FHT (equation 15),

$$F_i \approx \sum_{j=1}^m f(x_j/r) w_j g(x_j) = \sum_{j=1}^m f(x_j/r) \hat{g}(x_j) \ ,$$

but with various bells and whistles applied (using the so-called Shanks transformation in the form of a routine called ϵ-algorithm (*[Shanks_1955]*, *[Wynn_1956]*; implemented with algorithms from *[Trefethen_2000]* and *[Weniger_1989]*).

This function is based on *get_CSEM1D_FD_QWE.m*, *qwe.m*, and *getBesselWeights.m* from the source code distributed with *[Key_2012]*.

The function is called from one of the modelling routines in `model`. Consult these modelling routines for a description of the input and output parameters.

> **Returns fEM** : array
>
>> Returns frequency-domain EM response.
>
> **kcount** : int
>
>> Kernel count.
>
> **conv** : bool
>
>> If true, QWE converged. If not, maxint might have to be set higher.

empymod.transform.**fft**(*fEM*, *time*, *freq*, *ftarg*)

Fourier Transform using a Cosine- or a Sine-filter.

It follows the Filter methodology *[Anderson_1975]*, see *fht* for more information.

The function is called from one of the modelling routines in `model`. Consult these modelling routines for a description of the input and output parameters.

This function is based on *get_CSEM1D_TD_FHT.m* from the source code distributed with *[Key_2012]*.

> **Returns tEM** : array
>
>> Returns time-domain EM response of *fEM* for given *time*.
>
> **conv** : bool
>
>> Only relevant for QWE, not for FFT.

empymod.transform.**fqwe**(*fEM*, *time*, *freq*, *qweargs*)

Fourier Transform using Quadrature-With-Extrapolation.

It follows the QWE methodology *[Key_2012]* for the Hankel transform, see *hqwe* for more information.

The function is called from one of the modelling routines in `model`. Consult these modelling routines for a description of the input and output parameters.

This function is based on *get_CSEM1D_TD_QWE.m* from the source code distributed with *[Key_2012]*.

Returns **tEM** : array

Returns time-domain EM response of *fEM* for given *time*.

conv : bool

If true, QWE converged. If not, maxint might have to be set higher.

empymod.transform.**fftlog**(*fEM*, *time*, *freq*, *ftarg*)

Fourier Transform using FFTLog.

FFTLog is the logarithmic analogue to the Fast Fourier Transform FFT. FFTLog was presented in Appendix B of *[Hamilton_2000]* and published at <http://casa.colorado.edu/~ajsh/FFTLog>.

This function uses a simplified version of *pyfftlog*, which is a python-version of *FFTLog*. For more details regarding *pyfftlog* see <https://github.com/prisae/pyfftlog>.

Not the full flexibility of *FFTLog* is available here: Only the logarithmic FFT (*fftl* in *FFTLog*), not the Hankel transform (*fht* in *FFTLog*). Furthermore, the following parameters are fixed:
- *mu* = 0.5 (sine-transform)
- *kr* = 1 (initial value)
- *kropt* = 1 (silently adjusts *kr*)
- *dir* = 1 (forward)

Furthermore, *q* is restricted to -1 <= q <= 1.

I am trying to get *FFTLog* into *scipy*. If this happens the current implementation will be replaced by the *scipy.fftpack.fftlog*-version.

The function is called from one of the modelling routines in model. Consult these modelling routines for a description of the input and output parameters.

Returns **tEM** : array

Returns time-domain EM response of *fEM* for given *time*.

conv : bool

Only relevant for QWE, not for FFTLog.

empymod.transform.**qwe**(*rtol*, *atol*, *maxint*, *inp*, *intervals*, *lambd=None*, *off=None*, *factAng=None*)

Quadrature-With-Extrapolation.

This is the kernel of the QWE method, used for the Hankel (*hqwe*) and the Fourier (*fqwe*) Transforms. See *hqwe* for an extensive description.

This function is based on *qwe.m* from the source code distributed with *[Key_2012]*.

empymod.transform.**get_spline_values**(*filt*, *inp*, *nr_per_dec=None*)

Return required calculation points.

empymod.transform.**fhti**(*rmin*, *rmax*, *n*, *q*)

Return parameters required for FFTLog.

filters – Digital Filters for FHT

Filters for the *Fast Hankel Transform* (FHT, *[Anderson_1982]*) and the *Fourier Sine and Cosine Transforms* *[Anderson_1975]*.

To calculate the *fhtfilter.factor* I used

```
np.around(np.average(fhtfilter.base[1:]/fhtfilter.base[:-1]), 15)
```

The filters *kong_61_2007* and *kong_241_2007* from *[Kong_2007]*, and *key_101_2009*, *key_201_2009*, *key_401_2009*, *key_81_CosSin_2009*, *key_241_CosSin_2009*, and *key_601_CosSin_2009* from *[Key_2009]* are taken from *DIPOLE1D*, *[Key_2009]*, which can be downloaded at marineemlab.ucsd.edu/Projects/Occam/1DCSEM. *DIPOLE1D* is distributed under the license GNU GPL version 3 or later. Kerry Key gave his written permission to re-distribute the filters under the Apache License, Version 2.0 (email from Kerry Key to Dieter Werthmüller, 21 November 2016).

The filters *anderson_801_1982* from *[Anderson_1982]* and *key_51_2012*, *key_101_2012*, *key_201_2012*, *key_101_CosSin_2012*, and *key_201_CosSin_2012*, all from *[Key_2012]*, are taken from the software distributed with *[Key_2012]* and available at software.seg.org/2012/0003. These filters are distributed under the SEG license.

`utils` – Utilites

Utilities for *model* such as checking input parameters.

This module consists of four groups of functions:

> 0. General settings

> 1. Class EMArray

> 2. Input parameter checks for modelling

> 3. Internal utilities

class empymod.utils.**EMArray**
> Subclassing an ndarray: add *amplitude* <amp> and *phase* <pha>.

Parameters realpart : array

1. Real part of input, if input is real or complex.

2. Imaginary part of input, if input is pure imaginary.

3. Complex input.

In cases 2 and 3, *imagpart* must be None.

imagpart: array, optional

Imaginary part of input. Defaults to None.

Examples

```
>>> import numpy as np
>>> from empymod.utils import EMArray
>>> emvalues = EMArray(np.array([1,2,3]), np.array([1, 0, -1]))
>>> print('Amplitude : ', emvalues.amp)
Amplitude :  [ 1.41421356  2.          3.16227766]
>>> print('Phase     : ', emvalues.pha)
Phase     :  [ 45.          0.         -18.43494882]
```

Attributes

amp	(ndarray) Amplitude of the input data.
pha	(ndarray) Phase of the input data, in degrees, lag-defined (increasing with increasing offset.) To get lead-defined phases, multiply *imagpart* by -1 before passing through this function.

empymod.utils.**check_time**(*time*, *signal*, *ft*, *ftarg*, *verb*)

Check time domain specific input parameters.

This check-function is called from one of the modelling routines in model. Consult these modelling routines for a detailed description of the input parameters.

Parameters time : array_like

Times t (s).

signal : {None, 0, 1, -1}

Source signal:

- None: Frequency-domain response

- -1 : Switch-off time-domain response

- 0 : Impulse time-domain response

- +1 : Switch-on time-domain response

ft : {'sin', 'cos', 'qwe', 'fftlog'}

Flag for Fourier transform, only used if *signal* != None.

ftarg : str or filter from empymod.filters or array_like,

Only used if *signal* !=None. Depends on the value for *ft*:

verb : {0, 1, 2, 3, 4}

Level of verbosity.

Returns time : float

Time, checked for size and assured min_time.

freq : float

Frequencies required for given times and ft-settings.

ft, ftarg

Checked if valid and set to defaults if not provided, checked with signal.

empymod.utils.**check_model**(*depth*, *res*, *aniso*, *epermH*, *epermV*, *mpermH*, *mpermV*, *verb*)
Check the model: depth and corresponding layer parameters.

This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

Parameters depth : list

Absolute layer interfaces z (m); #depth = #res - 1 (excluding +/- infinity).

res : array_like

Horizontal resistivities rho_h (Ohm.m); #res = #depth + 1.

aniso : array_like

Anisotropies lambda = sqrt(rho_v/rho_h) (-); #aniso = #res.

epermH, epermV : array_like

Relative horizontal/vertical electric permittivities epsilon_h/epsilon_v (-); #epermH = #epermV = #res.

mpermH, mpermV : array_like

Relative horizontal/vertical magnetic permeabilities mu_h/mu_v (-); #mpermH = #mpermV = #res.

verb : {0, 1, 2, 3, 4}

Level of verbosity.

Returns depth : array

Depths of layer interfaces, adds -infty at beginning if not present.

res : array

As input, checked for size.

aniso : array

As input, checked for size. If None, defaults to an array of ones.

epermH, epermV : array_like

As input, checked for size. If None, defaults to an array of ones.

mpermH, mpermV : array_like

As input, checked for size. If None, defaults to an array of ones.

isfullspace : bool

If True, the model is a fullspace (res, aniso, epermH, epermV, mpermM, and mpermV are in all layers the same).

empymod.utils.**check_frequency**(*freq*, *res*, *aniso*, *epermH*, *epermV*, *mpermH*, *mpermV*, *verb*)
    Calculate frequency-dependent parameters.

    This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

    > **Parameters** **freq** : array_like
    >
    > > Frequencies f (Hz).
    >
    > **res** : array_like
    >
    > > Horizontal resistivities rho_h (Ohm.m); #res = #depth + 1.
    >
    > **aniso** : array_like
    >
    > > Anisotropies lambda = sqrt(rho_v/rho_h) (-); #aniso = #res.
    >
    > **epermH, epermV** : array_like
    >
    > > Relative horizontal/vertical electric permittivities epsilon_h/epsilon_v (-); #epermH = #epermV = #res.
    >
    > **mpermH, mpermV** : array_like
    >
    > > Relative horizontal/vertical magnetic permeabilities mu_h/mu_v (-); #mpermH = #mpermV = #res.
    >
    > **verb** : {0, 1, 2, 3, 4}
    >
    > > Level of verbosity.
    >
    > **Returns** **freq** : float
    >
    > > Frequency, checked for size and assured min_freq.
    >
    > **etaH, etaV** : array
    >
    > > Parameters etaH/etaV, same size as provided resistivity.
    >
    > **zetaH, zetaV** : array
    >
    > > Parameters zetaH/zetaV, same size as provided resistivity.

empymod.utils.**check_hankel**(*ht*, *htarg*, *verb*)
    Check Hankel transform parameters.

    This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

    > **Parameters** **ht** : {'fht', 'qwe'}
    >
    > > Flag to choose the Hankel transform.
    >
    > **htarg** : str or filter from empymod.filters or array_like,
    >
    > > Depends on the value for *ht*.
    >
    > **verb** : {0, 1, 2, 3, 4}
    >
    > > Level of verbosity.
    >
    > **Returns** ht, htarg
    >
    > > Checked if valid and set to defaults if not provided.

empymod.utils.**check_opt**(*opt*, *loop*, *ht*, *htarg*, *verb*)
    Check optimization parameters.

    This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

> **Parameters** **opt** : {None, 'parallel', 'spline'}
>
>> Optimization flag.
>>
>> **loop** : {None, 'freq', 'off'}
>>
>>> Loop flag.
>>>
>>> **ht** : str
>>>
>>>> Flag to choose the Hankel transform.
>>>>
>>>> **htarg** : array_like,
>>>>
>>>>> Depends on the value for *ht*.
>>>>>
>>>>> **verb** : {0, 1, 2, 3, 4}
>>>>>
>>>>>> Level of verbosity.
>
> **Returns** **use_spline** : bool
>
>> Boolean if to use spline interpolation.
>>
>> **use_ne_eval** : bool
>>
>>> Boolean if to use *numexpr*.
>>>
>>> **loop_freq** : bool
>>>
>>>> Boolean if to loop over frequencies.
>>>>
>>>> **loop_off** : bool
>>>>
>>>>> Boolean if to loop over offsets.

empymod.utils.**check_dipole**(*inp*, *name*, *verb*)

> Check dipole parameters.

> This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

> **Parameters** **inp** : list of floats or arrays
>
>> Pole coordinates (m): [pole-x, pole-y, pole-z].
>>
>> **name** : str, {'src', 'rec'}
>>
>>> Pole-type.
>>>
>>> **verb** : {0, 1, 2, 3, 4}
>>>
>>>> Level of verbosity.
>
> **Returns** **inp** : list
>
>> List of pole coordinates [x, y, z].
>>
>> **ninp** : int
>>
>>> Number of inp-elements

empymod.utils.**check_bipole**(*inp*, *name*)

> Check di-/bipole parameters.

> This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.

> **Parameters** **inp** : list of floats or arrays
>
>> Coordinates of inp (m): [dipole-x, dipole-y, dipole-z, azimuth, dip] or. [bipole-x0, bipole-x1, bipole-y0, bipole-y1, bipole-z0, bipole-z1].

> **name** : str, {'src', 'rec'}
>
> > Pole-type.
>
> **Returns inp** : list
>
> > As input, checked for type and length.
>
> > **ninp** : int
> >
> > > Number of inp.
> >
> > **ninpz** : int
> >
> > > Number of inp depths (ninpz is either 1 or ninp).
> >
> > **isdipole** : bool
> >
> > > True if inp is a dipole.

empymod.utils.**check_ab**(*ab*, *verb*)

> Check source-receiver configuration.
>
> This check-function is called from one of the modelling routines in model. Consult these modelling routines for a detailed description of the input parameters.
>
> > **Parameters ab** : int
> >
> > > Source-receiver configuration.
> >
> > **verb** : {0, 1, 2, 3, 4}
> >
> > > Level of verbosity.
> >
> > **Returns ab_calc** : int
> >
> > > Adjusted source-receiver configuration using reciprocity.
> >
> > **msrc, mrec** : bool
> >
> > > If True, src/rec is magnetic; if False, src/rec is electric.

empymod.utils.**get_abs**(*msrc*, *mrec*, *srcazm*, *srcdip*, *recazm*, *recdip*, *verb*)

> Get required ab's for given angles.
>
> This check-function is called from one of the modelling routines in model. Consult these modelling routines for a detailed description of the input parameters.
>
> > **Parameters msrc, mrec** : bool
> >
> > > True if src/rec is magnetic, else False.
> >
> > **srcazm, recazm** : float
> >
> > > Horizontal source/receiver angle (azimuth).
> >
> > **srcdip, recdip** : float
> >
> > > Vertical source/receiver angle (dip).
> >
> > **verb** : {0, 1, 2, 3, 4}
> >
> > > Level of verbosity.
> >
> > **Returns ab_calc** : array of int
> >
> > > ab's to calculate for this bipole.

empymod.utils.**get_geo_fact**(*ab*, *srcazm*, *srcdip*, *recazm*, *recdip*, *msrc*, *mrec*)

> Get required geometrical scaling factor for given angles.
>
> This check-function is called from one of the modelling routines in model. Consult these modelling routines for a detailed description of the input parameters.

Parameters ab : int

Source-receiver configuration.

srcazm, recazm : float

Horizontal source/receiver angle.

srcdip, recdip : float

Vertical source/receiver angle.

Returns fact : float

Geometrical scaling factor.

empymod.utils.**get_azm_dip**(*inp*, *iz*, *ninpz*, *intpts*, *isdipole*, *strength*, *name*, *verb*)

Get angles, interpolation weights and normalization weights.

This check-function is called from one of the modelling routines in model. Consult these modelling routines for a detailed description of the input parameters.

Parameters inp : list of floats or arrays

Input coordinates (m):

- [x0, x1, y0, y1, z0, z1] (bipole of finite length)

- [x, y, z, azimuth, dip] (dipole, infinitesimal small)

iz : int

Index of current di-/bipole depth (-).

ninpz : int

Total number of di-/bipole depths (ninpz = 1 or npinz = nsrc) (-).

intpts : int

Number of integration points for bipole (-).

isdipole : bool

Boolean if inp is a dipole.

strength : float, optional

Source strength (A):

- If 0, output is normalized to source and receiver of 1 m length, and source strength of 1 A.

- If != 0, output is returned for given source and receiver length, and source strength.

name : str, {'src', 'rec'}

Pole-type.

verb : {0, 1, 2, 3, 4}

Level of verbosity.

Returns tout : list of floats or arrays

Dipole coordinates x, y, and z (m).

azm : float or array of floats

Horizontal angle (azimuth).

dip : float or array of floats

> Vertical angle (dip).

g_w : float or array of floats

> Factors from Gaussian interpolation.

intpts : int

> As input, checked.

inp_w : float or array of floats

> Factors from source/receiver length and source strength.

empymod.utils.**get_off_ang**(*src*, *rec*, *nsrc*, *nrec*, *verb*)

> Get depths, offsets, angles, hence spatial input parameters.
>
> This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.
>
> > **Parameters src, rec** : list of floats or arrays
> >
> > > Source/receiver dipole coordinates x, y, and z (m).
> >
> > **nsrc, nrec** : int
> >
> > > Number of sources/receivers (-).
> >
> > **verb** : {0, 1, 2, 3, 4}
> >
> > > Level of verbosity.
> >
> > **Returns off** : array of floats
> >
> > > Offsets
> >
> > **angle** : array of floats
> >
> > > Angles

empymod.utils.**get_layer_nr**(*inp*, *depth*)

> Get number of layer in which inp resides.
>
> Note: If zinp is on a layer interface, the layer above the interface is chosen.
>
> This check-function is called from one of the modelling routines in `model`. Consult these modelling routines for a detailed description of the input parameters.
>
> > **Parameters inp** : list of floats or arrays
> >
> > > Dipole coordinates (m)
> >
> > **depth** : array
> >
> > > Depths of layer interfaces.
> >
> > **Returns linp** : int or array_like of int
> >
> > > Layer number(s) in which inp resides (plural only if bipole).
> >
> > **zinp** : float or array
> >
> > > inp[2] (depths).

empymod.utils.**printstartfinish**(*verb*, *inp=None*, *kcount=None*)

> Print start and finish with time measure and kernel count.

empymod.utils.**conv_warning**(*conv*, *targ*, *name*, *verb*)

> Print error if QWE did not converge at least once.
